(54) Inclusion complexes of steroids  
with  $\delta$ -cyclodextrin

(57) The title complexes have 3-100  
times the water-solubility of the  
uncomplexed steroids, e.g.  
spironolactone, nortestosterone,  
methyltestosterone, androst-4-ene-  
3, 17-dione, progesterone, Reichstein  
S, Reichstein S acetate, 16 $\alpha$ -methyl-  
Reichstein S, Hydrocortisone, estrone,  
dexamethasone, prednisolone,  
triamcinolone, pregnenetriolone  
triacetate.

Pharmaceutical compositions  
containing the title complexes are free  
from the nephrotoxic effects of the  
corresponding  $\alpha$ - and  $\beta$ -cyclodextrin  
complexes owing to the faster  
enzymatic decomposition of  
 $\delta$ -cyclodextrin.

## SPECIFICATION

Inclusion complexes of steroids with  $\gamma$ -cyclodextrin

- 5 The invention relates to the inclusion complexes of steroids poorly soluble in water with  $\gamma$ -cyclodextrin, to a process for their preparation and pharmaceutical compositions containing them as active ingredient.
- 10 Cyclodextrins are formed from starch by the cyclodextrin transglycolase enzyme. The cyclodextrin molecules consist of 6, 7 or 8 glucopyranose unit forming  $\alpha$ -1,4-glucose units. Structurally they are characterized by a special arrangement of the hydroxyl groups. All the secondary hydroxyls are situated on one edge of the ring, while all the primary hydroxyls are placed on the other edge of that ring. Therefore the outer surface of the ring is essentially hydrophilic which ensures that the cyclodextrins are water-soluble. On the other hand the inner surface of the rings has a hydrophobic character since in that part of the molecule only hydrogen atoms and glucosidal oxygen bridges are to be found. Consequently, apolar molecules of appropriate shape and size penetrate into the cave inside the cyclodextrin and form cyclodextrin inclusion complexes, which may be isolated in a microcrystalline form.
- The physical and chemical stability of the guest molecules is essentially improved by the formation of inclusion complexes and in numerous cases it has been observed that this results in an increase in the solubility as well.
- With respect to  $\alpha$ -cyclodextrin the following solubility increasing effects have been published:
- 35 Lautsch, Rauchut, Grimm and Broeser [Z. Naturforsch., 12b, 307-314 [1957]] described that the solubility of acetylene in an aqueous  $\alpha$ -cyclodextrin solution increases to 1.2-times its original value; according to Cohen and Lach [J. Pharm. Sci., 52, 132-136 [1963]] the solubility of hydroxybenzoic acids and parabenes is increased to 1.25 to 6-times the original values; Lach and Cohen [J. Pharm. Sci., 52, 137 [1963]] observed in the case of 11 structurally different compounds a 1.1 to 3.4-times increase in solubility in an aqueous  $\alpha$ -cyclodextrin solution; according to Lach and Chin [J. Pharm. Sci., 53, 69-73 [1964]] for substituted benzoic acids the increase was 1.1 to 10-fold; Uekama, Hirayama, Matsuo and Koinuma [Chem. Lett., 1978, 703-706] reported that the solubility of tolbutamide in an  $\alpha$ -cyclodextrin solution increases to twice of the original value; Uekama and Hirayama [Chem. Bull., 26, 1195-1200 [1978]] published a 2.8-times solubility increase for prostaglandin - F<sub>2</sub> - alpha while according to Yamada, Inaba and Ikeda [J. Pharm. Sci., 68, 1059 [1979]] in case of prostaglandin - E<sub>1</sub> methyl esters a 27.5-times solubility increase was achieved by using  $\alpha$ -cyclodextrin.
- $\beta$ -Cyclodextrin has also been reported to possess analogous properties. For example Lautsch, Bandel and Broeser [Z. Naturforsch., 11b, 282-291] increased the solubility of an azo-dye to 6 times the original value; Cohen and Lach [J. Pharm. Sci., 52, 132-136 [1963]] achieved a 1.1 to 2-times solubility increase in case of hydrobenzoic acids and para-

- benes; Lach and Cohen [J. Pharm. Sci., 52, 137 [1963]] reported a 1.03 to 3.6-times solubility increase for various, structurally different compounds in the presence of  $\beta$ -cyclodextrin; according to Lach and Chin [J. Pharm. Sci., 53, 924-927 [1964]] the solubility of benzocaine was increased to twice its original value; Thakkar, Kuehn, Perrin and Wilham [J. Pharm. Sci., 61, 1841-1843 [1972]] reported a 1.3 to 3.3-times solubility increase for barbitals; Uekama, Matsuo, Hirayama, Yamaguchi, Imamura and Ichibagase [Chem. Pharm. Bull., 27, 398-402 [1972]] observed a 3-fold solubility increase for acetohexamide; according to Uekama and Otagiri [Chem. Pharm. Bull., 23, 201-208 [1975]] the solubility of flufenamic acid could be increased by  $\beta$ -cyclodextrin by a factor of 6.6; according to Uekama, Hirayama, Matsuo and Koinuma [Chem. Lett., 1978, 703-706] in a  $\beta$ -cyclodextrin solution the solubility of tolbutamide can be increased by a factor of 2.75; Frank and Cho [J. Pharm. Sci., 67, 1665-1668 [1978]] could increase the solubility of prostaglandin-E<sub>2</sub> to four times its original level; Uekama and Hirayama [Chem. Bull., 26 1195-1200 [1978]] increased the solubility of prostaglandin - F<sub>2</sub> - alpha by a factor of 3.8; Uekama, Hirayama, Yamada, Inaba and Ikeda [J. Pharm. Sci., 68, 1059 [1979]] reported that the solubility of prostaglandin - E<sub>1</sub> - methyl esters in water could be increased by a factor of 7.5; Pauli and Lach [J. Pharm. Sci., 54, 1745-1750 [1965]] increased the solubility of seven different aromatic carboxylic acids in an aqueous  $\beta$ -cyclodextrin solution by a factor of 1.05 to 4.2.

Of the steroids only testosterone and cortisone acetate has been tested [Lach and Pauli, J. Pharm. Sci., 55, 32-38 [1966]] and a 2.7 and 4.3 times increase, respectively was observed in the water-solubility in the presence of  $\beta$ -cyclodextrin.

Testing the effect of  $\gamma$ -cyclodextrin on the water-solubility of various steroids we observed surprisingly high increases. In relatively dilute [several per centage]  $\gamma$ -cyclodextrin solutions the water-solubility of various steroids was increased by about a factor of 3 to 100, generally 3.4 to 66.

In this way injectable steroid solutions can easily be prepared. Hereinbelow we list the saturation concentrations of aqueous  $\gamma$ -cyclodextrin solutions of several steroidal compounds:

methyltestosterone	7.5 mg./ml.
spironolactone	3.0 mg./ml.
115 hydrocortisone	5.0 mg./ml.
prednisolone	8.2 mg./ml.
dexamethasone	6.0 mg./ml.
triamcinolone	14.6 mg./ml.

These compounds could hitherto be applied as oily, intramuscular injections, of organic solutions where there was always a danger of toxicity, or their water-soluble derivatives had to be prepared. By forming  $\gamma$ -cyclodextrin complexes of these and other steroidal compounds injectable aqueous solutions can be prepared without any difficulty.

A further essential advantage of  $\gamma$ -cyclodextrin complexes over the inclusion complexes with  $\alpha$ - or  $\beta$ -cyclodextrin is that the enzymatic decomposition of  $\alpha$ - and  $\beta$ -cyclodextrin is very slow, therefore they have a nephrotoxic effect when administered

parenterally. Therefore from  $\alpha$ - and  $\beta$ -cyclodextrin complexes of steroids could not be prepared injectable compositions even if their solubility increasing effect were satisfactory. On the other hand,

- 5  $\beta$ -cyclodextrin has such a flexible molecular structure that the rate of its enzymatic decomposition is about 100 times higher than that of  $\beta$ -cyclodextrin; accordingly, the cyclodextrin ring is quickly split in the living organism and is metabolized just as starch  
10 or linear cyclodextrins which are essential components of human foods. Therefore, when  $\gamma$ -cyclodextrins are administered parenterally, the danger of toxicity can practically be neglected.

- Also the absorption of orally or locally administered steroids can effectively be increased by  
15  $\gamma$ -cyclodextrin.

- The inclusion complexes of steroids with  $\gamma$ -cyclodextrin have a hydrophilic character, they moisten with water immediately and the steroids do  
20 not float on the surface of the water. The saturation concentration is achieved quicker, generally by an order of magnitude, than without  $\gamma$ -cyclodextrin and the saturation concentration is about 10 to 100-times higher than that of the steroids alone.

- The invention relates to the inclusion complexes of steroids poorly soluble in water with  
25  $\gamma$ -cyclodextrin. In this context the term "steroids poorly soluble in water" is used to relate to steroidal compounds, which are insoluble in water or have, for practical purposes an unsuitably low water-solubility. As a result of forming inclusion complexes with  $\gamma$ -cyclodextrin the steroids poorly soluble in water and having a hydrophobic character become more hydrophilic, hence both the rate of  
30 dissolution and the saturation concentration increase by 1 to 2 orders of magnitude; accordingly the biological applicability of the compounds is improved.

- Cyclodextrin inclusion complexes can be prepared  
40 in several different ways. For example the cyclodextrins can be kneaded with the compounds to be included in the presence of a small amount of water; or an organic solution of the compounds to be complexed may be shaken with an aqueous cyclodextrin  
45 solution; or the desired inclusion complexes can be prepared by coprecipitation from a common homogenous solution of the two components. In the case of steroids complexes of satisfactory quality can be prepared by the latter procedure.

- According to another aspect of the invention there is provided a process for the preparation of inclusion complexes of steroids poorly soluble in water with  
50  $\gamma$ -cyclodextrin. According to this procedure a solution of the steroids in an alcohol containing one to 3 carbon atoms, ether or acetone is admixed with an  
55 aqueous solution of  $\gamma$ -cyclodextrin between room temperature and the boiling point of the solvent employed, the mixture is cooled and the precipitated steroid- $\gamma$ -cyclodextrin complex is isolated.

- According to a preferred embodiment of the above procedure an aqueous  $\gamma$ -cyclodextrin solution is prepared at a temperature of 50 to 70°C, the steroid is dissolved in an equal volume of a 96% by vol. ethanol solution at the same temperature and the  
60 two solutions are admixed. Under these conditions

- at 50 to 70°C a homogeneous solution is formed, which is then cooled to room temperature under vigorous stirring in 3 hours. By cooling the precipitation of the crystals of the inclusion complex is initiated. To complete the procedure the mixture is kept  
70 at a temperature of 0°C for additional 12 hours. The precipitated product is filtered off or separated from the mother liquor by centrifuging, whereupon it is dried at 80°C under atmospheric pressure or at 40°C  
75 *in vacuo*.

- Solutions can be prepared also by admixing the steroids with a 1 to 10% by weight, preferably 3 to 5% by weight aqueous solution of  $\gamma$ -cyclodextrin. Thus injectable solutions are prepared. This process  
80 is a further subject of the present invention.

- The steroids may generally be complexed with  $\gamma$ -cyclodextrin to form inclusion complexes efficiently by using two or more moles of  $\gamma$ -cyclodextrin per mole of steroid.

- If the steroid is used in a higher proportion, it is only partially included in the  $\gamma$ -cyclodextrin molecules.

- To summarise, the conversion of steroids to complexes with  $\gamma$ -cyclodextrin has the following advantages:

- a/ Aqueous [injectable] solutions having considerably higher steroid concentration than before can be prepared.

- b/  $\alpha$ -Cyclodextrin has an about two orders of magnitude better enzymatic metabolism than either-  
95 or  $\beta$ -cyclodextrin, hence it can be administered parenterally.

- c/ The inclusion complexes of steroids with  $\gamma$ -cyclodextrin moisten quickly and efficiently with water, the velocity of their dissolution and frequently even the saturation concentration is improved by orders of magnitude [powder ampoule injections can be prepared], therefore in case of tablets or ointments a quicker and better absorption is  
100 expected.

- According to a still further aspect of the invention there are provided pharmaceutical compositions containing the inclusion complexes of steroids poorly soluble in water with  $\gamma$ -cyclodextrin. The pharmaceutical compositions comprise the inclusion complexes optionally in association with conventional carriers, excipients and optionally further conventional additives and can be prepared by generally known techniques for the preparation of  
115 pharmaceutical formulations.

- The invention will now be illustrated in greater detail by the following specific Examples, which are given for illustration and not limitation of the invention. In the Examples the ratios given for the complexes are molar ratios and the percentages, if not  
120 otherwise stated, are by weight.

#### Example 1

##### The preparation of aqueous steroidal solutions

- Various steroids were shaken in  $\alpha$ -cyclodextrin  
125 solutions of various concentrations at 25°C for 3 hours. The steroids were always employed in an excess amount, i. e. at the end of the experiments there was some solid steroid in the solution. After filtering off this solid the dissolved steroid amount  
130 was determined. As shown in Tables I-VII the solubil-

ity does not show a continuous increase as a function of the  $\gamma$ -cyclodextrin concentration but a more or less sharp maximum can be observed. Depending on the steroid there is a narrower or broader

- 5 -cyclodextrin concentration range in which the increase of solubility is the greatest. Exceeding this optimum range the solubility of the steroid starts decreasing again but still remains considerably higher than without  $\gamma$ -cyclodextrin.

- 10 Tables I-VII illustrate the dependence of the

water-solubility of various steroids on the concentration of  $\gamma$ -cyclodextrin.

- According to the data set forth in Tables I-VII a maximum water-solubility can be achieved in a 3 to 15 5%  $\gamma$ -cyclodextrin solution. In order to compare the increase in the solubility of various steroids said compounds were shaken in a 10% [i.e.  $7.51 \times 10^{-2}$  moles/lit.]  $\gamma$ -cyclodextrin solution at 25°C for 3 hours, whereupon the quantity of the dissolved steroids 20 was determined. The results are given in Table VIII.

#### Example 2

##### The preparation of a spironolactone - $\gamma$ - cyclodextrin complex [molar ratio: 1:2]

- 1531 mg. [1.03 x 10<sup>-3</sup> moles] of  $\gamma$ -cyclodextrin containing altogether 15% crystal and included water are dissolved in 4 ml. of water at 60°C. 213 mg. [5.1 x 10<sup>-4</sup> moles] of spironolactone are separately dissolved in 4 ml. of a 96% ethanol at 60°C. The two solutions are slowly admixed under continuous stirring.
- 10 In a short time the precipitation of the crystalline complex can be observed. The mixture is cooled to room temperature under vigorous stirring for 3 hours, whereupon it is kept at about 0°C for 12 hours. The crystalline product is filtered off and dried. 1476 mg. of the title complex are obtained containing 12% of spironolactone.

According to thermoanalytical measurements the product is an inclusion complex. This is supported also by the X-ray diffraction examinations, since on the diffractogram of the product intensive reflection

peaks are observed at an angle of 2  $\Theta$ , which is completely different from the results obtained with physical mixture.

##### Preparation of a complex with a molar ratio of 1:3

- 25 1539 mg. [1.03 x 10<sup>-3</sup> moles] of  $\gamma$ -cyclodextrin containing 15% of water are dissolved in 4 ml. of water at 60°C. 140 mg. [3.34 x 10<sup>-4</sup> moles] of spironolactone are separately dissolved in 4 ml. of a 96% ethanol at 60°C. The two solutions are admixed as described hereinabove, stirred, cooled and filtered.
- 30 1342 mg. of a complex containing 8.25% of spironolactone are obtained. According to thermoanalytical measurements the product is an inclusion complex. About 79.3% of the steroid added to the reaction mixture is isolated as a complex. A complex with a molar ratio of 1:3 should theoretically contain 9.7% of spironolactone.

##### Attempt to prepare a complex with a molar ratio of 1:1

- 40 660 mg. [4.43 x 10<sup>-4</sup> moles] of  $\gamma$ -cyclodextrin hav-

ing 15% water are dissolved in 5 ml. of water at 60°C. 200 mg. [ $4.8 \times 10^{-4}$  moles] of spironolactone are separately dissolved in 5 ml. of a 96% ethanol having a temperature of 60°C. The two solutions are admixed as described above, stirred, filtered and dried. 643.2 mg. of a product containing 22.7% of spironolactone are obtained. A 1:1 complex should theoretically contain 24.3% of spironolactone. The solid product contains only 69% of the steroid added to the reaction mixture and according to the thermoanalytical measurements a substantial amount of the spironolactone is present as a simple, physical mixture, i.e. in uncomplexed form.

**Preparation of a 1:2 spironolactone -  $\gamma$ -cyclodextrin complex by kneading in a 50% ethanolic medium**

1486 mg. [ $9.8 \times 10^{-4}$  moles] of  $\gamma$ -cyclodextrin having a humidity of 15% and 203 mg. [ $4.9 \times 10^{-4}$  moles] of spironolactone are thoroughly kneaded with 2 ml. of a 50% ethanol. During this procedure the evaporation loss is restored by adding 1 ml. of a 50% ethanol. The product is dried in an desiccator of 60°C. A homogenous complex containing 13.55% of active ingredient [theoretical: 13.85%] is obtained. The material loss is minimal.

To prove the formation of cyclodextrin inclusion complexes with thermoanalytical methods can generally be employed with good results. In case of steroids, however, the applicability of these methods is restricted since the decomposition of the steroids and  $\gamma$ -cyclodextrin often takes place in the same temperature range. In the case of spironolactone the complex formation is verified also by differential

scanning calorimetric studies, since if a physical mixture is present, an endothermic peak characteristic of spironolactone is observed at 203°C, while if a complex is formed this peak is lacking.

In case of the complexes prepared with a 1:2 or 1:3 molar ratio, it can be established that there is no free spironolactone present, but these experiments alone are not sufficient to find out whether in the complexes prepared with a molar ratio of 1:3 free cyclodextrin is present or a complex with a different crystalline structure is formed.

The dissolution of the steroids is substantially accelerated by the formation of complexes as illustrated by the following experiments.

To compare the dynamic dissolution velocity of spironolactone and a 1:2 spironolactone -  $\gamma$ -cyclodextrin complex 6 mg. of spironolactone and 18.6 mg. of the  $\gamma$ -cyclodextrin complex were added to 50 ml. of distilled water having a constant temperature of 25.0°C. The  $\gamma$ -cyclodextrin complex contained 12% of active ingredient. Under continuous stirring samples were taken, filtered and the concentration of dissolved spironolactone was determined by u.v. photometric measurements. During the experiments the free steroid was added to the system in an amount exceeding the water-solubility limit, while the amount of the complex was selected so that at a total dissolution of the dissolved active ingredient the concentration equals to the dissolution limit determined for the free steroid. The results are shown in Table IX.

**Table IX**  
Velocity of the dissolution of free spironolactone and spironolactone -  $\gamma$ -cyclodextrin complex at 25°C

Time [min]	Concentration of dissolved spironolactone [ $\mu\text{g/ml.}$ ]	
	Spironolactone	complex
1	8	30
3	14	43
5	20	43

15	35	43
20	39	44
30	42	44
60	44	43

**Example 3**

**The preparation of prednisolone -  $\gamma$ -cyclodextrin complex [molar ratio: 1:2]**

1550 mg. [ $1.02 \times 10^{-3}$  moles] of  $\gamma$ -cyclodextrin containing 15% of humidity are dissolved in 5 ml. of distilled water at 60°C. The solution is admixed with 185 mg. [ $5.1 \times 10^{-4}$  moles] of prednisolone in 5 ml. of a 96% ethanol of 60°C. The mixture is slowly cooled under continuous stirring. To complete crystallization the mixture is kept in a refrigerator for 12 hours. The product is filtered off and dried in an desiccator at 80°C. 1366 mg. of a complex are obtained containing 11.2% of active ingredient. [Calculated active ingredient concentration for a 1:2 complex: 12.2%].

82.7% of the prednisolone present in the reaction mixture is included in the complex.

The differential thermogravimetric spectrum of the product shows only a small peak at 278°C [e.g. the material loss is low], while in the corresponding spectrum of a physical mixture having the same active ingredient concentration a high peak is present at the same temperature indicating the decomposition of the steroid. The same conclusions can be drawn from the thermal evolution analysis [TEA] curves. From the complex only a small amount of decomposition product is evolved at 285°C, while in the case of a mechanical mixture a high peak can be observed at 285°C also on this curve. The differential

scanning calorimetric [DSC] curve of the physical mixture shows a high exothermic peak at 243°C which can be explained by the oxidation of prednisolone. On the DSC curve of the complex only a small effect can be observed at the same temperature. The complex character of the crystalline product was confirmed also by the X-ray diffraction

measurements.

The velocity of the dissolution of 30 mg. of prednisolone and 188 mg. of a  $\gamma$ -cyclodextrin complex thereof containing 11.2% of active ingredient [molar ratio: 1:2] was tested as described in Example 2. The results are set forth in Table X.

*Table X*

#### Example 4

##### 15 Preparation of a 1:2 complex of dexamethasone with $\gamma$ -cyclodextrin

Following the procedure described in Example 3 from 1496 mg. [ $9.8 \times 10^{-4}$  moles] of  $\gamma$ -cyclodextrin containing 15% of water and 196 mg. [ $4.9 \times 10^{-4}$  moles] of dexamethasone 1388 mg. of an inclusion complex were prepared containing 10.6% of active ingredient. [Calculated value for a 1:2 complex: 13.1%]. Yield for dexamethasone: 75%.

A 1:2 dexamethasone -  $\gamma$ -cyclodextrin complex can be prepared also by liophilization. 104 mg [ $2.65 \times 10^{-4}$  moles] of dexamethasone and 912 mg. [ $6.1 \times 10^{-4}$  moles] of  $\gamma$ -cyclodextrin [humidity: 13.6%] are dissolved in 40 ml. of a 50% ethanol solution at room temperature. The cloudy solution is filtered through

30 a glass filter and is subsequently liophilized. The product contains 11.5% of active ingredient. Yield: practically 100%. When heating at 250 to 290°C a substantially lower amount of organic substance is eliminated from the product than from a physical mixture having the same active ingredient concentration and the pure dexamethasone, respectively. From this one can conclude that the overwhelming majority of dexamethasone is present as a complex.

The velocity of the dissolution of 7.6 mg. of dexamethasone, 47.3 mg. of a complex containing 10.6% of active ingredient and 43.3 mg. of a liophilized complex containing 11.5% of active ingredient, was examined as described in Example 2. The results are shown in Table XI.

*Table XI*

60	357	359

} limit value at  
3 min.

} limit value at  
60 min.

25 The formation of complexes was verified also by a simple qualitative method. In 100 ml. glasses 50-50 ml. of distilled water were filled and placed on black paper. On the surface of the water 3 mg. of steroid, 30 mg. of a steroid -  $\gamma$ -cyclodextrin complex, and a physical mixture having the same active ingredient concentration, respectively were sprinkled. The free steroid floats on the surface of the water showing its hydrophobic character and remains on the surface as a white layer even after a strong shaking. The physical mixture essentially shows the same character as the free steroid. The complex tested sinks down to the bottom of the glass in about 3 to 5 sec-

onds and disintegrates there or disintegration takes place already on the surface of water. The dissolution can be accelerated and completed by a slight movement of the glass. The significant difference was observed in the case of every complex prepared according to Examples 2 to 11.

#### Example 7

#### 45 Preparation of a 1:2 complex of progesterone with $\gamma$ -cyclodextrin

Following the procedure described in Example 7 from 1532 mg. [ $102 \times 10^{-3}$  moles] of  $\gamma$ -cyclodextrin and 158 mg. [ $5.04 \times 10^{-4}$  moles] of progesterone 1220 mg. of a complex containing 10.2% of active

ingredient [calculated: 10.82%] are obtained. Yield calculated for progesterone: 78.7%.

#### Example 8

#### Preparation of a 1:2 complex of nortestosterone with $\gamma$ -cyclodextrin

Following the procedure described in Example 3 starting from 1493 mg. [ $9.95 \times 10^{-4}$  moles] of  $\gamma$ -cyclodextrin containing 13.6% of water and 136 mg. [ $4.95 \times 10^{-4}$  moles] of nortestosterone 1307 mg. of a complex containing 9.2% of active ingredient [calculated: 9.57%] are obtained. Yield calculated for nortestosterone: 88.4%.

#### Example 9

#### Preparation of a 1:2 complex of oestrone with $\gamma$ -cyclodextrin

Following the procedure described in Example 3 starting from 1504 mg. [ $10^{-3}$  moles] of  $\gamma$ -cyclodextrin containing 13.6% water and 130 mg. [ $4.8 \times 10^{-4}$  moles] of oestrone 1190 mg. of a complex containing 9.25% of active ingredient [calculated: 9.45%] are obtained. Yield for oestrone: 84.7%.

#### Example 10

#### Preparation of a 1:2 complex of triamcinolone base with $\gamma$ -cyclodextrin

Following the procedure described in Example 3 starting from 1498 mg. [ $9.97 \times 10^{-4}$  moles] of  $\gamma$ -cyclodextrin having a water content of 13.6% and 213 mg. [ $4.9 \times 10^{-4}$  moles] of triamcinolone base 1247 mg. of a complex containing 13.9% of active

ingredient are obtained [calculated: 14.39%]. Yield calculated for the triamcinolone base: 81.4%.

#### Example 11

#### Preparation of a 1:2 complex of pregnenetriolone triacetate

Following the procedure described in Example 3 but using 8 ml. of distilled water and 8 ml. of a 96% ethanol from 1520 mg. [ $1.01 \times 10^{-3}$  moles] of  $\gamma$ -cyclodextrin and 232 mg. [ $4.9 \times 10^{-4}$  moles] of pregnenetriolone triacetate 1173 mg of a complex containing 15.1% of active ingredient [calculated: 15.46%] are obtained. Yield calculated for the steroid: 76.3%.

#### Example 12

#### Comparison of the effect of $\alpha$ - and $\gamma$ -cyclodextrin on the solubility of steroids in water

Into aqueous  $\alpha$ - and  $\gamma$ -cyclodextrin solutions having the same concentration [ $7.5 \times 10^{-2}$  moles/lit] solid steroids were added in a large excess. As soon as the dissolution equilibrium was established, the total steroid concentration of the solution phase was determined. Since starting from  $\beta$ -cyclodextrin such concentrated solutions [10%] cannot be prepared, for  $\beta$ -cyclodextrin we could not give any comparative data.

It had been observed that  $\gamma$ -cyclodextrin had a considerably higher solubility-increasing effect than  $\alpha$ -cyclodextrin. The results are shown in Table XIV.

Table XIV

Steroid	Solubility				
	water mg./ml. [ $S_0$ ]	$\alpha$ -CD solv. mg./ml. [ $S_1$ ]	7.7.10 <sup>-2</sup> mol. $S_1/S_0$	$\gamma$ -CD solv. mg./ml. [ $S_2$ ]	$S_2/S_0$

#### Example 13

#### Comparative study of the solubility of the complexes of the same steroids with different cyclodextrins

The complexes of progesterone, methyltestosterone and triamcinolone acetonide with  $\alpha$ -,  $\beta$ - and  $\gamma$ -cyclodextrin, respectively were prepared following the conventional methods outlined hereinabove.

The complexes precipitating from an 50% homogeneous hot ethanolic solution upon cooling were filtered off, dried and the active ingredient concentrations and compositions were determined. The solubility of the complexes was examined in distilled water at 37°C [Table XV].

An equilibrium dissolution was achieved in about 2 to 5 minutes. For these test samples containing 10 mg. of active ingredient/ml. were used. The results

show that for all three steroids the  $\gamma$ -cyclodextrin complexes has the highest solubility.

Table XV

steroid	solubility of steroids at 37°C [mg./ml.]	complex	$\alpha$ -CD	$\beta$ -CD complex	$\gamma$ -CD

**Example 14****Use of inclusion complexes of steroids with  $\gamma$ -cyclodextrin in pharmaceutical preparations**

The steroid- $\gamma$ -cyclodextrin inclusion complexes according to the invention can be converted into pharmaceutical compositions by the conventional methods of the preparation of pharmaceuticals. In the followings the preparation of certain tablets, ointments and injections is illustrated.

**25-mg. spironolactone tablets****Composition:**

200 mg. of spironolactone -  $\gamma$  - cyclodextrin complex

60 mg. of lactose

29 mg. of potato starch

9 mg. of talc

2 mg. of magnesium stearate pro tablet

The quantity of spironolactone -  $\gamma$  - cyclodextrin complex relates to a spironolactone content of

12.5%.

Total weight of a tablet: 300 mg.

The tablets are prepared by the conventional dry granulation technique.

**10-mg. hydrocortisone tablets****Composition:**

85 mg. of hydrocortisone -  $\gamma$  - cyclodextrin complex

20 mg. of carboxymethyl starch

135 mg. of microcrystalline cellulose

3 mg. of stearic acid

7 mg. of talc pro tablet

The quantity of the hydrocortisone -  $\gamma$  - cyclodextrin complex relates to a hydrocortisone content of 11.8%.

Total weight of a tablet: 250 mg.

**1.5-mg. oestrone tablets****Composition:**

16 mg. of oestrone -  $\gamma$  - cyclodextrin complex

120 mg. of microcrystalline cellulose

34 mg. of starch

3 mg. of stearic acid

2 mg. of colloidal silicic acid

5 mg. of vinylpyrrolidone and vinylacetate copolymerisate pro tablet.

45 The quantity of the oestrone -  $\gamma$  - cyclodextrin complex relates to an oestrone content of 9.3%. Total weight of a tablet: 180 mg.

The tablets are prepared in a conventional way by direct pressing.

**5-mg. prednisolone tablets****Composition:**

45 mg. of prednisolone -  $\gamma$  - cyclodextrin complex

120 mg. of microcrystalline cellulose

31.5 mg. of starch

55 1.5 mg. of colloidal silicic acid

2 mg. of magnesium stearate pro tablet

The quantity of the prednisolone -  $\gamma$  - cyclodextrin complex relates to a prednisolone content of 11.2%. Total weight of a tablet: 200 mg.

60 The tablets are prepared in a conventional manner.

**0.5% prednisolone ointment**

To 4.777 g. of Unguentum simplex ointment containing 6% of lanalcohol, 3% of cetylstearyl alcohol and 12% white vaseline (RTM) 223 mg. of a prednisolone -  $\gamma$  - cyclodextrin complex are added. The quantity of the complex relates to a prednisolone content of 11.2%.

**1% hydrocortisone ointment**

To 4.576 g. of Unguentum simplex ointment 424 mg. of hydrocortisone -  $\gamma$  - cyclodextrin complex are admixed. The quantity of the complex relates to a hydrocortisone content of 11.8%.

**0.5% hydrocortisone eye ointment**

To 4.778 g. of Oculentum simplex ointment containing 5% of lanacol, 25% of liquid paraffin and 70% of ophthalmologic vaseline 10 mg. of chloramphenicol and 121 mg. of hydrocortisone -  $\gamma$  - cyclodextrin complex are added. The quantity of the complex relates to a hydrocortisone content of

80 11.8%.

*5-mg. dexamethasone aqueous injection*

Composition:

- |   |   |          |
|---|---|----------|
|   | Dexamethasone - $\gamma$ - cyclodextrin complex | 47.2 mg. |
| 5 | sodium chloride                                 | 21 mg.   |
|   | distilled water in injection quality ad         | 3 ml.    |
- The complex contains 10.6% of dexamethasone. Sodium chloride and the dexamethasone -  $\gamma$  - cyclodextrin complex are dissolved in freshly distilled
- 10 water of injection quality. The solution is made up with water to the desired volume, filtered and filled in ampoules. Sterilization is carried out by autoclave at 120°C for 20 minutes.

CLAIMS

- 15 1. Inclusion complexes of steroids poorly soluble in water with  $\gamma$ -cyclodextrin.
2. Inclusion complexes as claimed in claim 1 wherein the steroid is selected from:
- 20 methyltestosterone
- spironolactone,
- pregnenetriolone triacetate
- hydrocortisone
- prednisolone,
- dexamethasone,
- 25 triamcinolone.
3. Inclusion complexes as claimed in claim 1 or claim 2, wherein the steroid:  $\gamma$ -cyclodextrin molar ratio is in the range 1:2 to 1:3.
4. A spironolactone -  $\gamma$  - cyclodextrin inclusion
- 30 complex having a molar ratio of 1:2.
5. Inclusion complexes as claimed in any preceding claim as herein specifically described.
6. Inclusion complexes as claimed in any preceding claim as herein specifically described in any of
- 35 Examples 1 to 13.
7. A process for the preparation of inclusion complexes as claimed in any preceding claim, which comprises admixing a solution of the steroid in a C<sub>1-3</sub> alkanol, ether or acetone with an aqueous solution of  $\gamma$ -cyclodextrin at a temperature between
- 40 room temperature and the boiling point of the solvent employed, and subsequently cooling the mixture thus obtained and isolating the precipitated steroid -  $\gamma$  - cyclodextrin complex.
- 45 8. A process as claimed in claim 7 wherein the steroid and  $\gamma$ -cyclodextrin are used in a molar ratio in the range 1:1 to 1:10 (steroid :  $\gamma$ -cyclodextrin).
9. A process as claimed in claim 7 or claim 8 wherein the steroid and  $\gamma$ -cyclodextrin are used in a
- 50 molar ratio in the range 1:2 to 1:3 (steroid :  $\gamma$ -cyclodextrin).
10. A process as claimed in any one of claims 7 to 9 substantially as herein described.
11. A process as claimed in any one of claims 7 to
- 55 10 substantially as herein described in any one of Examples 1 to 13.
12. Pharmaceutical compositions containing steroids, comprising as active ingredient a inclusion complex as claimed in claim 1 in association with
- 60 one or more conventional pharmaceutical carriers or excipients, optionally together with one or more further additives.
13. Pharmaceutical compositions as claimed in claim 12 when in a form suitable for parenteral
- 65 administration.

14. Pharmaceutical compositions as claimed in claim 12, when in a form suitable for oral or local administration.

70 15. Pharmaceutical composition as claimed in claim 12 substantially as herein described.

16. Pharmaceutical composition as claimed in claim 12 substantially as herein described in Example 14.

75 17. A process for the preparation of injectable pharmaceutical compositions as claimed in claim 13 wherein the steroid is admixed with a 1 to 10% by weight aqueous solution of  $\gamma$ -cyclodextrin.

18. A process as claimed in claim 17 wherein a 3 to 5% by weight aqueous solution of  $\gamma$ -cyclodextrin is used.

80 19. A process as claimed in claim 17 or claim 18 for the preparation of pharmaceutical compositions substantially as herein described.

20. Inclusion complexes as claimed in claim 1 when prepared by a process as claimed in claim 7.

85 21. Inclusion complexes in claim 1 for use in a method of treatment of patients by administering to the said patient one or more steroids poorly soluble in water.
